

Week 6 - Friday

**COMP 2230**

# Last time

---

- More set theory review
- Russell's Paradox

Questions?

---

# Assignment 3

---

# Logical warmup

- You have 15 bags
- How many marbles do you need so that you can have a different number of marbles in each bag?

# Halting Problem

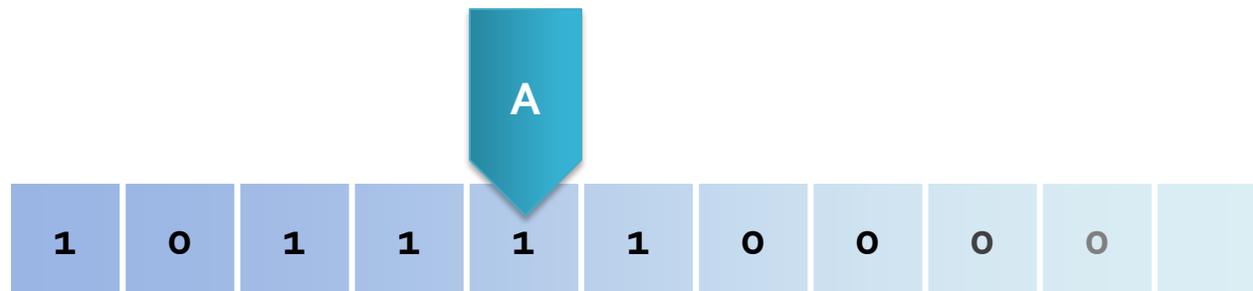

---

# Applying the idea again

- It turns out that the idea behind Russell's Paradox has practical implications
- It wasn't new, either
- Cantor had previously used a diagonal argument to show that there are more real numbers than rational numbers
- But, unexpectedly, Turing found an application of this idea for computing

# Turing machine

- A Turing machine is a mathematical model for computation
- It consists of a head, an infinitely long tape, a set of possible states, and an alphabet of characters that can be written on the tape
- A list of rules saying what it should write and should it move left or right given the current symbol and state

# Church-Turing thesis

- If an algorithm exists, a Turing machine can perform that algorithm
- In essence, a Turing machine is the most powerful model we have of computation
- Power, in this sense, means the *ability* to compute some function, **not** the *speed* associated with its computation

# Halting problem

- Given a Turing machine and input  $x$ , does it reach the halt state?
- First, recognize that we can encode a Turing machine as input for another Turing machine
  - We just have to design a system to describe the rules, the states, etc.
- We want to design a Turing machine that can read another

# Halting problem problems

- Imagine we have a Turing machine  $H(m, x)$  that takes the description of another Turing machine  $m$  and its input  $x$  and returns 1 if  $m$  halts on input  $x$  and 0 otherwise
- Now, construct a machine  $H'(m, x)$  that runs  $H(m, x)$ , but, if  $H(m, x)$  gives 1, then  $H'(m, x)$  infinitely loops, and if  $H(m, x)$  gives 0, then then  $H'(m, x)$  returns 1
- Let's say that  $d$  is the description of  $H'(m, x)$
- What happens when you run  $H'(d, d)$ ?

# Halting problem conclusion

- Clearly, a Turing machine that solves the halting problem **can't** exist
- Essentially, the problem of deciding if a problem is computable is itself uncomputable
- Therefore, there are some problems (called **undecidable**) for which there is no algorithm
- Not an algorithm that will take a long time, but **no algorithm**
- If we find such a problem, we are stuck
- ... unless someone can invent a more powerful model of computation

# And it gets worse!

- Gödel used diagonalization again to prove that it is impossible to create a consistent set of axioms that can prove everything about the set of natural numbers
- As a consequence, you can create a system that is complete but not consistent
- Or you can create a system that is consistent but not complete
- Either way, there are principles in math in general that are true but impossible to prove, at least with any given system
- You might as well give up on math now

# Cardinality

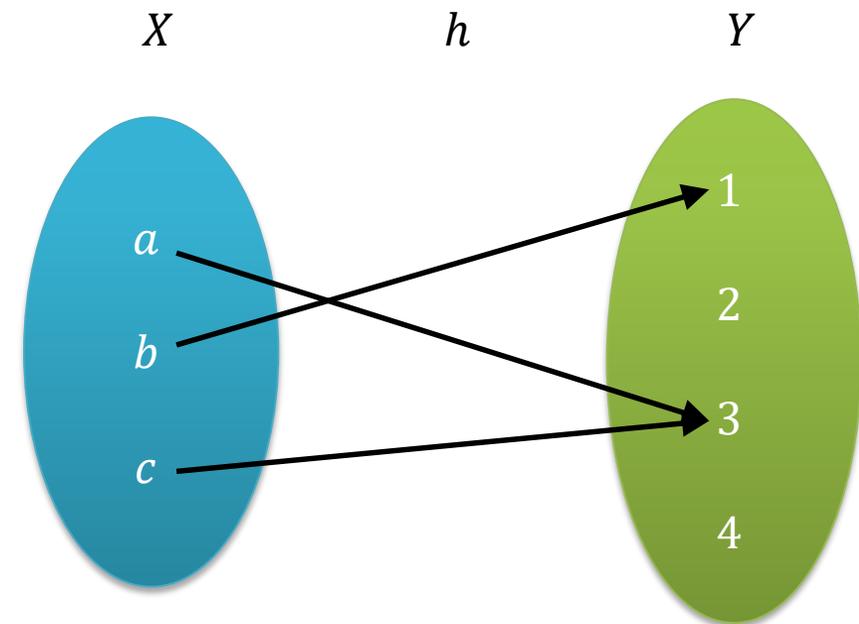

---

# Cardinality

- **Cardinality** gives the number of things in a set
- Cardinality is:
  - **Reflexive:**  $A$  has the same cardinality as  $A$
  - **Symmetric:** If  $A$  has the same cardinality as  $B$ ,  $B$  has the same cardinality as  $A$
  - **Transitive:** If  $A$  has the same cardinality as  $B$ , and  $B$  has the same cardinality as  $C$ ,  $A$  has the same cardinality as  $C$
- For finite sets, we could just count the things to determine if two sets have the same cardinality

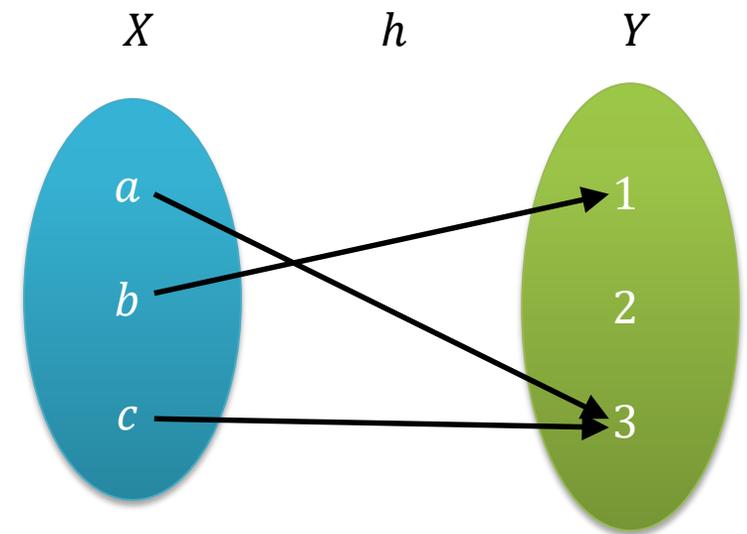

# One-to-one functions

- Let  $F$  be a function from  $X$  to  $Y$
- $F$  is **one-to-one** (or **injective**) if and only if:
  - If  $F(x_1) = F(x_2)$  then  $x_1 = x_2$
- Is  $f(x) = x^2$  from  $\mathbb{Z}$  to  $\mathbb{Z}$  one-to-one?
- Is  $f(x) = x^2$  from  $\mathbb{Z}^+$  to  $\mathbb{Z}$  one-to-one?
- Is  $h(x)$  one-to-one?

# Onto functions

- Let  $F$  be a function from  $X$  to  $Y$
- $F$  is **onto** (or **surjective**) if and only if:
  - $\forall y \in Y, \exists x \in X$  such that  $F(x) = y$
- Is  $f(x) = x^2$  from  $\mathbb{Z}$  to  $\mathbb{Z}$  onto?
- Is  $f(x) = x^2$  from  $\mathbb{R}^+$  to  $\mathbb{R}^+$  onto?
- Is  $h(x)$  onto?

# Bijjective functions

- A **bijjective** function  $F: X \rightarrow Y$  is both:
  - One-to-one (injective)
  - Onto (surjective)
- Every element in  $X$  is mapped to exactly one element in  $Y$  and vice versa
- Such functions have inverses

# Cardinality for infinite sets

- Because we can't just count the number of things in infinite sets, we need a more general definition
- For any sets  $A$  and  $B$ ,  $A$  has the same cardinality as  $B$  iff there is a bijective mapping  $A$  to  $B$
- Thus, for any element in  $A$ , it corresponds to exactly one element in  $B$ , and everything in  $B$  has exactly one corresponding element in  $A$

# Cardinality example

- Show that the set of positive integers has the same cardinality as the set of all integers
- **Hint:** Create a bijective function from all integers to positive integers
- **Hint 2:** Map the positive integers to even integers and the negative integers to odd integers

# Countability

- A set is called **countably infinite** if it has the same cardinality as  $\mathbb{Z}^+$
- You have just shown that  $\mathbb{Z}$  is countable
- It turns out that (positive) rational numbers are countable too, because we can construct a table of their values and move diagonally across it, numbering values, skipping numbers that have been listed already

	1	2	3	4
1	$\frac{1}{1}$	$\frac{1}{2}$	$\frac{1}{3}$	$\frac{1}{4}$
2	$\frac{2}{1}$	<del><math>\frac{2}{2}</math></del>	$\frac{2}{3}$	<del><math>\frac{2}{4}</math></del>
3	$\frac{3}{1}$	$\frac{3}{2}$	<del><math>\frac{3}{3}</math></del>	$\frac{3}{4}$
4	$\frac{4}{1}$	<del><math>\frac{4}{2}</math></del>	$\frac{4}{3}$	<del><math>\frac{4}{4}</math></del>

# Uncountability

- So if the number of integers is the same as the number of rational numbers, that must also be the same as the number of real numbers, right?
- **Wrong.**
- There are **a lot** more real numbers
- The number of real numbers is called uncountable
- It's a larger infinity than the number of integers
- But it's not the largest infinity ...
  - There is no largest infinity

# Proving that there are more real numbers

- First, let's think about just the real numbers between 0 and 1 (not counting 1)
- Let's just put them in some list, in totally random order
- As long as we can make a numbered list, we can make a bijection with positive integers

Order	Number
1	0.58506706117215100 ...
2	0.30188097640659700 ...
3	0.05925831116503750 ...
4	0.09291012351774230 ...
5	0.79408644654174900 ...
6	0.09792740408760530 ...
7	0.72995316404639900 ...
8	0.26184376611267000 ...
9	0.42370325559805900 ...
...	...

# Proof continued

- Let's create a number by going through the list and make a number by taking digit  $i$  from column  $i$  and adding 1 to it (rolling over to 0 if it's 9)
- For our list: 0.610098276 ...
- Now, is our number in the list?
- No! It's impossible, since it's different from every single number in at least one place
- Thus, our assumption that we could make a list of all the real numbers was false (because we couldn't even make a list of the ones from 0 to 1)

Order	Number
1	0.58506706117215100 ...
2	0.30188097640659700 ...
3	0.05925831116503750 ...
4	0.09291012351774230 ...
5	0.79408644654174900 ...
6	0.09792740408760530 ...
7	0.72995316404639900 ...
8	0.26184376611267000 ...
9	0.42370325559805900 ...
...	...

# Names

- For future reference, the cardinality of positive integers, countable infinity, is named  $\aleph_0$  (pronounced aleph null)
- The cardinality of real numbers, the first uncountable infinity (because there are infinitely many uncountable infinities), is named  $\aleph_1$  (pronounced aleph 1)

# Relations

---

# Relations

- **Relations** are generalizations of functions
- In a function, an element of the domain must map to exactly one element of the co-domain
- In a relation, an element from one set can be related to any number (from zero up to infinity) of other elements
- Like functions, we're usually going to focus on binary relations
- We can define any binary relation between sets  $A$  and  $B$  as a subset of  $A \times B$

# Notation

- For binary relation  $R$ ,
  - $x R y \leftrightarrow (x, y) \in R$
- Let  $R$  be a relation from  $\mathbb{Z}$  to  $\mathbb{Z}$  such that  $(x, y) \in R$  iff  $x - y$  is even
  - Is  $1 R 3$ ?
  - Is  $2 R 3$ ?
  - Is  $2 R 2$ ?
- Let  $C$  be a relation from  $\mathbb{R}$  to  $\mathbb{R}$  such that  $(x, y) \in C$  iff  $x^2 + y^2 = 1$ 
  - Is  $(1, 0) \in C$ ?
  - Is  $0 C 0$ ?
  - Is  $\left(-\frac{1}{2}, \frac{\sqrt{3}}{2}\right) \in C$ ?

# Function or not?

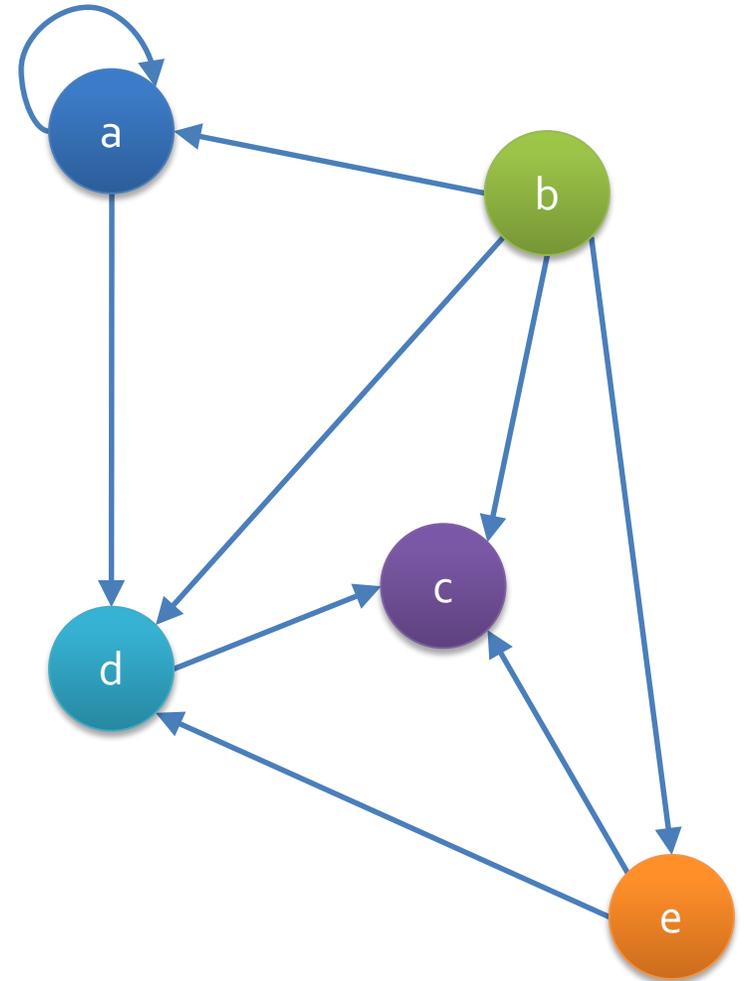

- Consider the sets  $A = \{2, 4, 6\}$  and  $B = \{1, 3, 5\}$
- Let  $R$  be the relation  $\{(2,5), (4,1), (4,3), (6,5)\}$ 
  - Draw the arrow diagram for  $R$
  - Is  $R$  a function?
- Let  $S$  be the relation for all  $(x, y) \in A \times B$ ,  $(x, y) \in S$  iff  $y = x + 1$ 
  - Draw the arrow diagram for  $S$
  - Is  $S$  a function?
- $x^2 + y^2 = 1$  on real numbers is not a function for both reasons

# Inverses

- We've relaxed things considerably by moving from functions to relations
- All relations have inverses (just reverse the order of the ordered pairs)
- Example
  - Let  $A = \{2,3,4\}$  and  $B = \{2,6,8\}$
  - For all  $(x, y) \in A \times B, x R y \leftrightarrow x \mid y$
  - List the ordered pairs in  $R$
  - List the ordered pairs in  $R^{-1}$

# Directed graphs

- A directed graph describes a relationship between nodes
- One way to record a graph is as a matrix
- We can also think of a directed graph as a relation from a set to itself
- What's the relation for this directed graph?

# Upcoming

---

# Next time...

- Reflexivity
- Symmetry
- Transitivity
- Equivalence relations

# Reminders

- Work on Assignment 3
  - Due next Friday
- Read 8.2 and 8.3
